Module 1: Communications in a Connected World

Networking Essentials (NETESS)

Module Objectives

****Objective:**** Explain the concept of network communication.

	Medium to large networks, such as those used by corporations and schools, can have many locations with hundreds or thousands of interconnected hosts.
on	Describe network data.
ghput	The internet is a network of networks that connects hundreds of millions of computers world-wide.
rs	Explain the roles of clients and servers in a network.
nts	Explain the roles of network infrastructure devices.

1.1 Network Types Everything is Online

The internet has become such a part of everyday life that we almost take it for granted. Normally, when people use the term internet, they are not referring to the physical connections in the real world. Rather, they tend to think of it as a formless collection of connections. It is the “place” people go to find or share information.

Who Owns “The Internet”?

The internet is not owned by any individual or group. The internet is a worldwide collection of interconnected networks (internetwork or internet for short), cooperating with each other to exchange information using common standards.

Local Networks

Small home networks connect a few computers to each other and to the internet.

The SOHO network allows computers in a home office or a remote office to connect to a corporate network, or access centralized, shared resources.

Medium to large networks, such as those used by corporations and schools, can have many locations with hundreds or thousands of interconnected hosts.

The internet is a network of networks that connects hundreds of millions of computers world-wide.

Mobile Devices

Smart phones combine the functions of many different products together, such as a telephone, camera, GPS receiver, media player, and touch screen computer.

Tablets come with on-screen keyboards, so users are able to do many of the things they used to do on their laptop computer, such as composing emails or browsing the web.

A smartwatch can connect to a smart phone to provide the user with alerts and messages and other functions, such as heart rate monitoring and counting steps, can help people who are wearing

the device to track their health.

A wearable computer in the form of glasses, such as Google Glass, contains a tiny screen that displays information to the wearer in a similar fashion to the Head-Up Display (HUD) of a fighter pilot.

Connected Home Devices

With a connected security system, many items in a home, such as lighting and climate controls, can be monitored and configured remotely using a mobile device.

Household appliances such as refrigerators, ovens, and dishwashers can be connected to the internet.

A smart TV can be connected to the Gaming consoles can connect to the internet to access content without the internet to download games and play need for TV service provider with friends online. equipment.

Other Connected Devices

Many modern cars, known as Smart Cars, can connect to the internet to access maps, audio and video content, or information about a destination.

Radio frequency identification (RFIDs) tags can be placed in or on objects to track them or monitor sensors for many conditions.

Connected sensors can provide Medical devices such as pacemakers, temperature, humidity, wind speed, insulin pumps, and hospital monitors barometric pressure, and soil moisture provide users or medical professionals with data. Actuators can then be automatically direct feedback or alerts when vital signs triggered based on current conditions are at specific levels.

Types of Personal Data

The following categories are used to classify types of personal data: This is created and explicitly shared by individuals, such as social network profiles. Volunteered data This type of data might include video files, pictures, text or audio files.

This is captured by recording the actions of individuals, such as location data when Observed data using cell phones.

This is data such as a credit score, which is based on analysis of volunteered or observed Inferred data data.

The Bit

Did you know that computers and networks only work with binary digits, zeros and ones? Each bit can only have one of two possible values, 0 or 1. The term bit is an abbreviation of “binary digit” and represents the smallest piece of data. Humans interpret words and pictures, computers interpret only patterns of bits. Each group of eight bits, such as the representations of letters and numbers, is known as a byte. Using the American Standard Code for Information Interchange (ASCII), each character is represented by eight bits. For example:

Capital letter: A = 01000001

**Num

**Spe

Co
Tra

must

across the network media to its destination. Media refers to the physical medium on which the signals are transmitted. Examples of media are copper wire, fiber-optic cable, and electromagnetic waves through the air. A signal consists of electrical or optical patterns that are transmitted from one connected device to another. There are three common methods of signal transmission used in networks:

Transmission is achieved by Electrical signals representing data as electrical pulses on copper wire.

Transmission is achieved by converting Optical signals the electrical signals into light pulses.

Transmission is achieved by using Wireless signals infrared, microwave, or radio waves through the air.

1.3 Bandwidth and Throughput

Bandwidth is the capacity of a medium to carry data. Digital bandwidth measures the amount of data that can flow from one place to another in a given amount of time. Bandwidth is typically measured in the number of bits that (theoretically) can b

Like bandwidth, throughput is the measure of the transfer of bits across the media over a given period of time. However, due to a number of factors, throughput does not usually match the specified bandwidth. Many factors influence throughput including:

The amount of data being sent and received over the connection

The types of data being transmitted

The latency created by the number of network devices encountered between source and destination Latency refers to the amount of time, including delays, for data to travel from one given point to another.

1.4 Clients and Servers

Clients and Server Roles

Clients are computer hosts that have software installed that enables the hosts to request and display the information obtained from the server. Servers are hosts that have software installed which enable them to provide information, like email or web pages, to other hosts on the network.

Unit of Bandwidth		Type	
		Email	The email server runs email server software. Clients use mail client software.
Bits per second		Web	The web server runs web server software. Clients use browser software.
Kilobyte: Thousands of bits per second		File	The file server stores corporate and user files in a central location. The client uses file sharing software to access files.
Megabyte: Millions of bits per second		Mbps	1 Mbps = 1,000,000 bps = 106bps
Gigabyte: Billions of bits per second		Gbps	1 Gbps = 1,000,000,000 bps = 109bps
Terabyte: Trillions of bits per second		Tbps	1 Tbps = 1,000,000,000,000 bps = 112bps

Peer-to-Peer Networks

In a peer-to-peer network, all computers function as the servers and clients on the network.

This type of network is called a peer-to-peer (P2P) network. The simplest P2P network consists of two directly connected computers using either a wired or wireless connection.

****Advantages of P2P:****

Easy to set up

Less complex than other networks

Lower cost because network devices and dedicated servers may not be required

Can be used for simple tasks such as transferring files and sharing printers

****Disadvantages of P2P:****

No central administration

Not as secure as other networks

Not scalable

All devices may act as both clients and server which can slow their performance

Peer-to-Peer Applications

A P2P application allows a device to act as both a client and a server within the same communication, as shown in the figure. In this model, every client is a server and every server is a client. P2P applications require that each end device provide a user interface and run a background service. In the figure, both clients can simultaneously send and receive messages.

Multiple Roles in the Network

A computer with server software can provide services simultaneously to one or many clients, as shown in the figure. Additionally, a single computer

can run multiple types of server software. In a home or small business, it may be necessary for one computer to act as a file server, a web server, and an email server.

1.5 Network Components

Network Infrastructure

The network infrastructure contains three categories of hardware components, as shown in the figure:

End devices

Intermediate devices

Network media

End Devices

The network devices that people are most familiar with are called end devices, or hosts. These devices form the interface between users and the underlying communication network. Some examples of end devices are as follows:

Computers (workstations, laptops, file servers, web servers)

Network printers

Telephones and teleconferencing equipment

Security cameras

Mobile devices (such as smart phones, tablets, PDAs, and wireless debit/credit card readers and barcode scanners)

In this lab, you will complete the following objectives:

Record all the different network-attached devices in your home or classroom.

Investigate how each device connects to the network to send and receive information.

Create a diagram showing the topology of your network.

Label each device with its function within the network.

1.6 Communications in a Connected World Summary

What Did I Learn in this Module?

The internet is a worldwide collection of interconnected networks cooperating with each other to exchange information using common standards.

Some types of networks that you may use are small home, SOHO, medium to large networks such as those created by corporations and schools, and the internet.

Mobile devices include smart phones, tablets, smart watches, and smart glasses.

Connected home devices include security systems, smart appliances and TVs, and gaming consoles.

Other connected devices include smart cars, RFIDs, sensors/actuators, and medical devices.

Types of personal data are categorized as volunteered, observed, and inferred.

Each bit can only have one of two possible values, 0 or 1. Each group of eight bits is known as a byte.

There are three common methods of signal transmission used in networks: electrical signals, optical signals, and wireless signals.

Bandwidth is typically measured in the number of bits that (theoretically) can be sent across the media in a second.

Many factors influence throughput including: the amount of data being sent and received over the connection, the types of data being transmitted, and the latency created by the number of network devices encountered between source and destination. You can measure your throughput by going to [speedtest.net](https://www.speedtest.net).

Clients are computer hosts that have software installed that enables the hosts to request and display the information obtained from the server. Servers are hosts that have software installed which enable them to provide information, like email or web pages, to other hosts on the network.

The simplest P2P network consists of two directly connected computers using either a wired or wireless connection.

A P2P application allows a device to act as both a client and a server within the same communication.

A computer with server software can provide services simultaneously to one or many clients.

Additionally, a single computer can run multiple types of server software.

The network infrastructure contains three categories of hardware components: end devices, intermediate devices, and network media.

The network devices that people are most familiar with are called end devices, or hosts. These devices form the interface between users and the underlying communication network.
